# Modern supercomputers

## Exponential rise of supercomputer power

→ we may reach soon technological/financial/environmental barriers

### Supercomputer Power (FLOPS)

The growth of supercomputer power, measured as the number of floating-point operations carried out per second (FLOPS) by the largest supercomputer in any given year. (FLOPS) is a measure of calculations per second for floating-point operations. Floating-point operations are needed for very large or very small real numbers, or computations that require a large dynamic range. It is therefore a more accurate measure than simply instructions per second.

# Lecture 1 : Quantum Circuits

- Presentations of a quantum circuit
- Single qubit : structure and operation (gates)
- Multi-qubit case : Universal set of gates
- The Measurement
- Physical realizations

# What is a quantum circuit ?

A **quantum circuit** executes the most common type of **quantum algorithms**

There exists other types! e.g., quantum annealing/analog quantum simulation (see Lecture 4)

# Single qubit : structure and operation (gates)

A qubit is a two-level quantum system (e.g., a two-level atom)

$$|\psi\rangle = c_0 |0\rangle + c_1 |1\rangle = \begin{bmatrix} c_0 \\ c_1 \end{bmatrix}$$

The state of a pure single qubit state can be represented by a Bloch vector **on the Bloch sphere**

$$|\psi\rangle = \cos\left(\frac{\theta}{2}\right) |0\rangle + \sin\left(\frac{\theta}{2}\right) e^{i\phi} |1\rangle$$

Classical bits are limiting cases of a qubit

# Single qubit gates

A single qubit gate converts a single qubit state to another single qubit state

$$q \text{ --- } \boxed{x} \text{ --- } \longrightarrow |\psi'\rangle = X |\psi\rangle$$

It is described by a unitary 2x2 matrix

$$UU^\dagger = 1$$

Or, equivalently, by a rotation on the Bloch sphere

# Important Single qubit gates

Pauli-X (X)

$$\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$$

Pauli-Y (Y)

$$\begin{bmatrix} 0 & -i \\ i & 0 \end{bmatrix}$$

Pauli-Z (Z)

$$\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}$$

Hadamard (H)

$$\frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}$$

Phase (S, P)

$$\begin{bmatrix} 1 & 0 \\ 0 & i \end{bmatrix}$$

$\pi/8$  (T)

$$\begin{bmatrix} 1 & 0 \\ 0 & e^{i\pi/4} \end{bmatrix}$$

**Question:** How can I create an equal-weight superposition state from the logical state  $|0\rangle$  ?

**Concatenation:** from left to right

# Multi-qubit case

Single qubit gates can act on parallel in a tensor product space

$$|0\rangle |0\rangle |0\rangle |0\rangle |0\rangle |0\rangle \rightarrow H |0\rangle |0\rangle H |0\rangle H |0\rangle H |0\rangle H |0\rangle$$

However, for a **universal quantum computer**, every global unitary operation of the  $2^N \times 2^N$  Hilbert space must be available

→ **Entangling operations required**

# Multi-qubit case

## Deutsch (1989):

A universal quantum computer can be realized with a set of single qubit and two qubit gates

The number of gates required to realize a certain operation is not necessarily small

**Efficient algorithms** are the one that require polynomial number of gates

# Important two-qubit gates

**Controlled Not  
(CNOT, CX)**

$$\begin{array}{c} |00\rangle \quad |01\rangle \quad |10\rangle \quad |11\rangle \\ \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{bmatrix} \end{array}$$

**Controlled Z (CZ)**

$$\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix}$$

**CNOT:** Flip the target qubit iff the control qubit is 1

**CZ:** minus sign if both qubits are 1

# Two qubit gates generate entanglement

## Creation of a Bell state

Two ingredients: Hadamard and CNOT

$$|0\rangle |0\rangle \rightarrow \frac{1}{\sqrt{2}}(|0\rangle + |1\rangle) |0\rangle \rightarrow \frac{1}{\sqrt{2}}(|00\rangle + |11\rangle)$$

We have created a maximally entangled state!

# Universal set of gates

Hadamard (H)

$$\frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}$$

Phase (S, P)

$$\begin{bmatrix} 1 & 0 \\ 0 & i \end{bmatrix}$$

$\pi/8$  (T)

$$\begin{bmatrix} 1 & 0 \\ 0 & e^{i\pi/4} \end{bmatrix}$$

Controlled Not  
(CNOT, CX)

$$\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{bmatrix}$$

This set is not unique

With one set, I can reach any state up to arbitrary accuracy

Note: phase gate is optional here (but convenient)

# Universal set of gates (example)

Build a CZ gate from a CNOT gate and two Hadamard gates

Hadamard (H)

$$\frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}$$

Controlled Not  
(CNOT, CX)

$$\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{bmatrix}$$

**Idea** : Change of basis from the Hadamard :  $HXH = Z$

**Exercise** : Check the identity

# Measurement

The measurement is often the last step of a quantum circuit

Mapping of quantum states to classical information (classical registers)

Very crucial step (readout errors)

Quantum operations based on measurement outcomes are possible (ex: error correction lecture 3)

# Measurement

A measurement is described by a set of  $n$  measurement outcomes  $(a_i)_{i=1,n}$

A quantum state is measured (and projected) in the state  $|a_i\rangle$  with probability  $|\langle a_i | \psi \rangle|^2$

In a quantum circuit, measurements in the 'computational basis',

**Histogram obtained after 1024 repetitions of the circuit**

$$|\langle s | \psi \rangle|^2$$

Bit string  $s$

# Measurement (examples)

Measurement of a **superposition state** (in the computational basis)

A single shot is not generically sufficient to characterize a quantum state  
A single measurement basis is also not always sufficient

# Measurement (examples)

**Non-destructive measurement** (very important for the next lectures..)

**Question :**

What is the final state of the first qubit  $q_0$  ???

$$|\psi\rangle = \frac{1}{\sqrt{2}}(|00\rangle + |11\rangle) \quad \text{Bell state}$$

# Measurement (examples)

**Full measurement** of a multi qubit state  
in the computational basis

Can you make sense of this  
measurement statistics ?

# Entertainment : Real quantum computers

## Ion traps

*Honeywell*

**The physics of these devices can be understood from atomic physics and quantum optics**

# Entertainment : Real quantum computers

## Superconducting quantum circuits

IBM Q™

The physics of these devices can be understood from solid-state physics and quantum optics

Many other platforms : NMR qubits, silicon qubits, Rydberg atoms

Grenoble is an important place: N. Roch, O. Buisson, T. Meunier, M. Vinet,.. <https://quantum.univ-grenoble-alpes.fr/>

# Real quantum computers

## Performances

**Table 2.** Summary of the achieved success probabilities for the implemented circuits, in percentages

Connectivity	Star shaped			Fully connected		
Hardware	Superconducting			Ion trap		
Success probability/%	Obs	Rand	Sys	Obs	Rand	Sys
Margolus	74.1(7)	82	75	90.1(2)	91	81
Toffoli	52.6(8)	78	59	85.0(2)	89	78
Bernstein–Vazirani	72.8(5)	80	74	85.1(1)	90	77
Hidden shift	35.1(6)	75	52	77.1(2)	86	57

Experimental Comparison of Two Quantum Computing Architectures," N. M. Linke, D. Maslov, M. Roetteler, S. Debnath, C. Figgatt, K. A. Landsman, K. Wright, C. Monroe, Proc. Natl. Acad. Sci. 114, 13 (2017).

**Performance** : Remarkable experimental progressess, quantum computers do exist (since 2005)!

**Speed** : 1 Hz for trapped ions, ~10 kHz for superconducting circuits

# Summary Lecture 1

- **Quantum circuits** are an architecture for developing quantum algorithms
- Basic ingredients : **qubits**, single qubit **gates** and two qubit gates (sufficient for universal quantum computation), and **measurement**
- **Different physical platforms** can now implement quantum circuits : trapped ion, superconducting quantum circuits, etc
